What is evidence of the effectiveness and safety of emergency department short stay units?

Evidence Summary No. 11
Developed as part of the OHRI-Champlain LHIN Knowledge to Action research program
February 2011
Disclaimer
The information in this report is a summary of available material and is designed to give readers (health systems stakeholders, policy and decision makers) a starting point in considering currently available research evidence. Whilst appreciable care has been taken in the preparation of the materials included in this publication, the authors do not warrant the accuracy of this document and deny any representation, implied or expressed, concerning the efficacy, appropriateness or suitability of any treatment or product. In view of the possibility of human error and advances of medical knowledge, the authors cannot and do not warrant that the information contained in these pages is current, accurate or complete. Accordingly, they shall not be responsible or liable for any errors or omissions that may be found in this publication. You should consult other sources in order to confirm the currency, accuracy and completeness of the information contained in this publication and, in the event that medical treatment is required you should take professional expert advice from a legally qualified and appropriately experienced medical practitioner.
What is the evidence of the effectiveness and safety of emergency department short stay units?

This report summarizes evidence of the effectiveness and safety of short stay units (SSU) in the emergency department (ED). Its intention is to support knowledge needs of stakeholders considering the implementation of SSUs in The Ottawa Hospital.

Key Messages

- Evidence from a moderately robust systematic review indicates SSUs may lead to improved clinical outcomes and efficiency in healthcare delivery. Yet, this systematic review is nearly a decade old. A rigorous and updated systematic review on this issue is strongly recommended.

- Most comparative evaluations of SSUs to date have involved before-and-after designs; consequently caution must be used in interpreting positive findings which may have also resulted from non-SSU improvement over time (e.g. changes in practice behaviors, increased hospital beds).

- There is a dearth of quality RCTs in both the literature assessing SSUs specifically, and ED overcrowding more globally. Evidence from the few RCTs reviewed are limited in generalizability due to the disease specific focus of the observation units evaluated (e.g. cardiac, asthma).

- There is limited evidence from one systematic review indicating that SSUs may lead to improved patient satisfaction in specific clinical contexts.

Who is this summary for?

This summary was undertaken for The Ottawa Hospital and is intended for use by local health systems stakeholders, policy-makers and decision-makers within The Ottawa Hospital.

Information about this evidence summary

This report covers a broad collection of literature and evidence sources with a search emphasis on systematic reviews.

As such, evidence summarized from systematic reviews is highlighted in blue boxes, like this one. Systematic reviews are generally favoured over other study designs, because they incorporate evidence from multiple primary studies, instead of reporting evidence from just one study.

This summary includes:

- Key findings from a broad collection of recent literature and evidence sources.

This summary does not include:

- Recommendations;
- Additional information not presented in the literature;
- Detailed descriptions of the interventions presented in the studies.

Many sections conclude with a “Bottom line” subsection that provides a statement summarizing the studies or aims to provide some context. These statements are not meant to address all of the evidence in existence on the subject, rather, only that which is featured in this document.

All papers summarized in this document are available by request to kkonnyu@ohri.ca.
I. Background
Emergency department (ED) overcrowding has been defined as “a situation where the demand for emergency services exceeds the ability to provide care in a reasonable amount of time” (Bond et al., 2006). ED overcrowding is a serious and ongoing issue across Canada; according to a 2006 survey of Canadian ED directors, 62% of respondents reported overcrowding to be a major or severe problem in 2004 and 2005 (Bond et al. 2006).

Short stay units (SSUs) have emerged as a potentially useful strategy for managing overcrowding in emergency departments. The theoretical benefit of SSUs is to ‘offload’ stable patients from the acute ED and to reduce the amount of unnecessary hospital admissions. Typically, the focus of these units are on 1) expected short treatments such as blood transfusions, 2) further diagnostic investigations to finalize a medical diagnosis, and 3) safe discharge into the community such as social work involvement. To prevent such units from being a ‘dumping grounds’, most SSUs have strict inclusion/admission criteria. Part of the difficulty is evaluating the value of SSUs is terminology – many other terms have been used to describe such units (e.g. Observation Units, Assessment Units, Clinical Decision Units). Typically though, SSUs are some type of extension of the ED with an overarching objective for improving “the quality of medical care through extended observation and treatment, while reducing inappropriate admissions and healthcare costs” (Daly et al. 2003).

The objective for this review was to conduct a rapid summary of the evidence related to the effectiveness and safety of ED SSUs. Its aim is to inform initiatives within The Ottawa Hospital and greater Champlain LHIN region attempting to address ED overcrowding. To frame the literature, we used the definition of SSUs as operationalized by our Ottawa Hospital stakeholder; specifically seeking and summarizing evidence that related to “an area of the hospital reserved for patients admitted directly from the ED who require a period of observation to resolve diagnostic uncertainty before being sent home or who are expected to recover within 48 hours or who require complex outpatient support arranged”.

II. Evidence
a. Evidence on SSUs specifically

A 2003 systematic review by Daly and colleagues in Australia assessed the evidence of short stay observation units with respect to efficiency of healthcare delivery and quality of services provided (Daly et al. 2003). Specifically, data from included studies was extracted according to the following domains: clinical outcomes, length of stay, representation rates, ED efficiency and costs of care. Notwithstanding the fact that the reviews’ search date is now over 10 years old, this is the best available synthesis of SSUs included in this evidence summary. Twelve studies (1 Canadian) comparing observation units with routine care were included; between-study heterogeneity prevented quantitative meta-analyses and findings could only be presented narratively. Table 1 from this report, summarizing the study characteristics and main conclusions is included below. Based on the evidence, the authors concluded that “[SSUs] have the potential to increase patient satisfaction, reduce length of stay, improve the efficiency of EDs and improve cost effectiveness. However, [SSUs] have commonly been implemented alongside new clinical protocols, and it is not possible to distinguish the relative benefits of each. As demand increases, providing effective and cost-efficient care will become increasingly important. [SSUs] may help organizations that are attempting to streamline patient care while maintaining their quality of service delivery”.

b. Evidence on solutions for overcrowding (SSUs one of multiple solutions)

9/11 A 2006 systematic review by the Canadian Agency for Drugs and Technologies in Health (CADTH) assessed the evidence on interventions to reduce overcrowding in the ED (Bond et al. 2006). SSUs were captured in two before-and-after studies and were associated with positive outcomes; one study reported a decrease in ED length of stay for treat-and-release patients, while the other reported a decrease of patients who left before being seen and the number of ED diversions (listed in “References of interest”). Based on this evidence, the review authors categorize SSUs as one of the several interventions for which “limited evidence suggests that these efforts to address overcrowding at an institutional level should be encouraged and monitored; they have a high chance of success” (see Table 2 for overview of interventions assessed). Of note, although the review attempted to assess the relative effectiveness of interventions aimed at improving ED overcrowding, the lack of direct comparisons, and the general trend for positive outcomes restricted this aim. Consequently the reviewers could only conclude that “many interventions of varying complexity, intensity, and duration have been applied in an attempt to alleviate or control ED overcrowding. While most seemed to reduce overcrowding, it is difficult to determine the relative value of these interventions, and the lack of comparison studies makes it impossible to say which ones work best”. As helpful direction for moving this evidence forward, they provide valuable recommendations for future studies including the need for comparable and representative comparison groups, blinded or unbiased outcome assessments, concurrent controls, comprehensive outcome assessment, and prospective design.
A 2008 systematic review by Hoot and Aronsky in the United States assessed the evidence pertaining to the causes, effects, and solutions of ED overcrowding (Hoot and Aronsky 2008); 4 studies assessing observation units (grouped under ‘solutions’) were included. Study findings were summarized narratively and were generally positive with respect to process outcomes (e.g., decreased length of stay, rate of ambulance diversion, and number of patients leaving without being seen). Of note, while systematic methods were employed, the literature search was not comprehensive (i.e., only searched a single database, excluded non-English titles and grey literature) and extracted quality assessments were not used to frame study results. Based on the complexity of the included studies, the reviewers “refrain from making strong conclusions…based primary on judgment rather than numeric inference” and consider the review to be of value more as a “structured overview of the relevant literature” to “guide interested readers to the original articles”. References of included observation unit studies are listed in “References of interest”.

**Bottom line:**
Evidence from two systematic reviews published in 2006 and 2008, respectively, assessed interventions aimed at reducing ED overcrowding. Several studies assessing SSUs were included and resulted in generally positive process outcomes. While the 2008 review by Hoot and Aronsky abstained from making conclusions based on the complexity of included studies, Bond and colleagues of the 2006 CADTH report conclude that there is sufficient (albeit limited) evidence to warrant implementation and further investigation of SSUs across intuitions in Canada.

### c. Other evidence

A 2006 systematic review by Boudreaux et al. in the United States assessed the evidence on performance improvement methods for increasing ED patient satisfaction. Observation units were captured as one of several interventions with “one supportive study (and no negative studies) demonstrating improvement in at least one indicator of satisfaction”. Of note, only observation units for specific conditions (e.g. asthma and chest pain) were captured in this review. References of included observation unit studies are listed in “References of interest”.

**Bottom line:**
There is limited evidence from one systematic review indicating that SSUs may lead to improved patient satisfaction in specific clinical contexts.

### III. Upcoming event

Readers of this report may be interested in attending the upcoming Western Emergency Department Overcrowding Conference to be held at the Sutton Place Hotel, in Edmonton, Alberta May 6 and 7th, 2011. On day 2 of this conference, there will be a presentation specific to ‘output solutions’ in which
KTA Evidence Summary: Emergency department short stay units

‘medical admission units’ is the first topic scheduled to be discussed (May 6th; 15:00-16:30). Registration information can be found at: http://uofa-hospital.gobigevent.com

Methods
Detailed search strategies were developed by an experienced Information Specialist (specific search terms available upon request). Searching was limited to the following databases:
- Biomed Central;
- Cochrane Database of Systematic Reviews (CDSR);
- Database of Abstracts of Reviews of Effects (DARE);
- National Health Service Economic Evaluation Databases (NHS EED).

Search concepts included Medical Subject Headings (MeSH) and non-thesaurus terms (i.e. text words). A ‘grey literature’ search was also conducted for potentially relevant studies by reviewing the web sites of relevant organizations and professional bodies (available upon request). Screening was conducted by two reviewers; quality assessment and extraction was done by one reviewer.

Based on the complexity, heterogeneity, and magnitude of the records, we chose to only include synthesized studies published during or after 2000. In addition, included citations had to have been published in English and be available in full text electronically. Of note, relevant primary studies however were screened and categorized, and are available upon request.
